## Description

Atmel's AT71200M is a progressive scan sensor based on charge-coupled device (CCD) technology. It can be used in a wide range of applications thanks to operating mode flexibility, very high definition and high dynamic range.

The nominal photosensitive area is made up of 2300 x 3500 useful pixels and is split into four independent zones that are driven separately by four independent four-phase clocksets. Thus the sensor can be used in up to 12 main modes.

The large format and high definition make the device suitable for any application requiring precision and accuracy.

The Bayer standard RGB color mosaic has been specially designed for colorimetric applications and the three colors balanced for a 3800K standard illuminant.

Two serial registers and four independent output amplifiers offer a high-frequency functionality of up to 10 frames per second and a 12-bit dynamic range.

## Color Mosaic Architecture

The color mosaic architecture corresponds to the Bayer standard represented by the following grid:

G	R	G	R
B	G	B	G
G	R	G	R
B	G	B	G

## Output Amplifiers

The charge packets are clocked to the output nodes and the charges are converted to voltages. The potential at the output node is read through two stage source follower amplifiers. Refer to Figure 3.

**Figure 3.** On-chip Output Amplifier Structure

## Absolute Maximum Ratings\*

Storage Temperature Range.....	-55°C to +150°C
Operating Temperature Range.....	-40°C to +85°C
Thermal Cycling.....	15°C/mn

\*NOTICE: Stresses above those listed under Absolute Maximum Ratings may cause permanent device failure. Functionality at or above these limits is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.

Electrical limits of applied signals are given in Table 5.

Shorting the video output to  $V_{SS}$  or  $V_{DD}$ , even temporarily, can permanently damage the output amplifier.

Due to MPP mode or negative voltages, image zone gates and region of interest gates do not include ESD protection. To avoid degradation, the devices (including pins and package) should be handled with a grounded bracelet and stored on conductive layer used for shipment.
